### 1.87

A car of mass 1775 kg travels with a velocity of $100 \mathrm{~km} / \mathrm{h}$. Find the kinetic energy. How high should it be lifted in the standard gravitational field to have a potential energy that equals the kinetic energy?

## Solution:

Standard kinetic energy of the mass is

$$
\begin{aligned}
\mathrm{KE}= & 1 / 2 \mathrm{~m} \mathrm{~V}^{2}=1 / 2 \times 1775 \mathrm{~kg} \times\left(\frac{100 \times 1000}{3600}\right)^{2} \mathrm{~m}^{2} / \mathrm{s}^{2} \\
& =1 / 2 \times 1775 \times 27.778 \mathrm{Nm}=684800 \mathrm{~J} \\
& =\mathbf{6 8 4 . 8} \mathbf{~ k J}
\end{aligned}
$$

Standard potential energy is
POT = mgh

$$
\mathrm{h}=1 / 2 \mathrm{~m} \mathrm{~V} \text { 2 } / \mathrm{mg}=\frac{684800 \mathrm{Nm}}{1775 \mathrm{~kg} \times 9.807 \mathrm{~m} / \mathrm{s}^{2}}=39.3 \mathrm{~m}
$$

You want a pot of water to boil at $105^{\circ} \mathrm{C}$. How heavy a lid should you put on the 15 cm diameter pot when $\mathrm{P}_{\mathrm{atm}}=101 \mathrm{kPa}$ ?

Solution:

Table B.1.1 at $105^{\circ} \mathrm{C}: \quad \mathrm{P}_{\text {sat }}=120.8 \mathrm{kPa}$

$$
\begin{aligned}
& \mathrm{A}=\frac{\pi}{4} \mathrm{D}^{2}=\frac{\pi}{4} 0.15^{2}=0.01767 \mathrm{~m}^{2} \\
& \mathrm{~F}_{\text {net }}=\left(\mathrm{P}_{\text {sat }}-\mathrm{P}_{\mathrm{atm}}\right) \mathrm{A}=(120.8-101) \mathrm{kPa} \times 0.01767 \mathrm{~m}^{2} \\
& =0.3498 \mathrm{kN}=350 \mathrm{~N} \\
& F_{\text {net }}=m_{\text {lid }} g \\
& \mathrm{~m}_{\text {lid }}=\mathrm{F}_{\text {net }} / \mathrm{g}=\frac{350}{9.807} \frac{\mathrm{~N}}{\mathrm{~m} / \mathrm{s}^{2}}=\mathbf{3 5 . 7} \mathbf{~ k g}
\end{aligned}
$$

Some lids are clamped on, the problem deals with one that stays on due to its weight.

### 3.132

We want to find the change in u for carbon dioxide between $50^{\circ} \mathrm{C}$ and $200^{\circ} \mathrm{C}$ at a pressure of 10 MPa. Find it using ideal gas and Table A. 5 and repeat using the B section table.

Solution:
Using the value of $\mathrm{C}_{\mathrm{vo}}$ for $\mathrm{CO}_{2}$ from Table A.5,
$\Delta \mathrm{u}=\mathrm{C}_{\mathrm{vo}} \Delta \mathrm{T}=0.653 \mathrm{~kJ} / \mathrm{kg}-\mathrm{K} \times(200-50) \mathrm{K}=\mathbf{9 7 . 9 5} \mathbf{~ k J} / \mathbf{k g}$
Using values of u from Table B3.2 at 10000 kPa , with linear interpolation between $40^{\circ} \mathrm{C}$ and $60^{\circ} \mathrm{C}$ for the $50^{\circ} \mathrm{C}$ value,

$$
\Delta u=u_{200}-u_{50}=437.6-230.9=206.7 \mathbf{k J} / \mathbf{k g}
$$

Note: Since the state $50^{\circ} \mathrm{C}, 10000 \mathrm{kPa}$ is in the dense-fluid supercritical region, a linear interpolation is quite inaccurate. The proper value for $u$ at this state is found from the CATT software to be 245.1 instead of 230.9. This results is

$$
\Delta u=u_{200}-u_{50}=437.6-245.1=192.5 \mathbf{k J} / \mathbf{k g}
$$

### 5.53

Find the maximum coefficient of performance for the refrigerator in your kitchen, assuming it runs in a Carnot cycle.

Solution:

The refrigerator coefficient of performance is

$$
\beta=\mathrm{Q}_{\mathrm{L}} / \mathrm{W}=\mathrm{Q}_{\mathrm{L}} /\left(\mathrm{Q}_{\mathrm{H}}-\mathrm{Q}_{\mathrm{L}}\right)=\mathrm{T}_{\mathrm{L}} /\left(\mathrm{T}_{\mathrm{H}}-\mathrm{T}_{\mathrm{L}}\right)
$$

Assuming $\quad \mathrm{T}_{\mathrm{L}} \sim 0^{\circ} \mathrm{C}, \quad \mathrm{T}_{\mathrm{H}} \sim 35^{\circ} \mathrm{C}$,

$$
\beta \leq \frac{273.15}{35-0}=7.8
$$

Actual working fluid temperatures must be such that

$$
\mathrm{T}_{\mathrm{L}}<\mathrm{T}_{\text {refrigerator }} \text { and } \mathrm{T}_{\mathrm{H}}>\mathrm{T}_{\text {room }}
$$

A refrigerator does not operate in a Carnot cycle. The actual vapor compression cycle is examined in Chapter 9.

### 7.86

A compressor in a commercial refrigerator receives R-410A at $-25^{\circ} \mathrm{C}$ and $\mathrm{x}=1$. The exit is at 1000 kPa and $20^{\circ} \mathrm{C}$. Is this compressor possible?

## Solution:

C.V. Compressor, steady state, single inlet and exit flow. For this device we also assume no heat transfer and $\mathrm{Z}_{\mathrm{i}}=\mathrm{Z}_{\mathrm{e}}$

From Table B.4.1 : $\quad h_{i}=269.77 \mathrm{~kJ} / \mathrm{kg}, \mathrm{s}_{\mathrm{i}}=1.0893 \mathrm{~kJ} / \mathrm{kg}-\mathrm{K}$
From Table B.4.2 : $\quad h_{e}=295.49 \mathrm{~kJ} / \mathrm{kg}, \mathrm{s}_{\mathrm{e}}=1.073 \mathrm{~kJ} / \mathrm{kg}-\mathrm{K}$
Entropy gives

$$
\mathrm{s}_{\text {gen }}=\mathrm{s}_{\mathrm{e}}-\mathrm{s}_{\mathrm{i}}-\int \mathrm{dq} / \mathrm{T}=1.073-1.0893-\int \mathrm{dq} / \mathrm{T}=\text { negative }
$$

The result is negative unless dq is negative (it should go out, but $\mathrm{T}<\mathrm{T}$ ambient) so this compressor is impossible

Borgnakke and Sonntag

### 9.99

A refrigerator has a steady flow of R-410A as saturated vapor at $-20^{\circ} \mathrm{C}$ into the adiabatic compressor that brings it to 1400 kPa . After the compressor, the temperature is measured to be $60^{\circ} \mathrm{C}$. Find the actual compressor work and the actual cycle coefficient of performance.
Solution:
Table B.4.1: $\quad \mathrm{h}_{1}=271.89 \mathrm{~kJ} / \mathrm{kg}, \quad \mathrm{s}_{1}=1.0779 \mathrm{~kJ} / \mathrm{kg} \mathrm{K}$

$$
\begin{aligned}
& \mathrm{P}_{2}=\mathrm{P}_{3}=1400 \mathrm{kPa}, \mathrm{~T}_{3}=18.88^{\circ} \mathrm{C}, \mathrm{~h}_{4}=\mathrm{h}_{3}=\mathrm{h}_{\mathrm{f}}=87.45 \mathrm{~kJ} / \mathrm{kg} \\
& \mathrm{~h}_{2 \mathrm{ac}}=330.07 \mathrm{~kJ} / \mathrm{kg}
\end{aligned}
$$

C.V. Compressor (actual)

Energy Eq.: $\quad \mathrm{w}_{\mathrm{C} \text { ас }}=\mathrm{h}_{2 \text { ac }}-\mathrm{h}_{1}=330.07-271.89=\mathbf{5 8 . 1 8} \mathbf{~ k J} / \mathbf{k g}$
C.V. Evaporator

Energy Eq.: $\quad \mathrm{q}_{\mathrm{L}}=\mathrm{h}_{1}-\mathrm{h}_{4}=\mathrm{h}_{1}-\mathrm{h}_{3}=271.89-87.45=184.44 \mathrm{~kJ} / \mathrm{kg}$

$$
\beta=\frac{\mathrm{q}_{\mathrm{L}}}{\mathrm{w}_{\mathrm{C} \mathrm{ac}}}=\frac{184.44}{58.18}=3.17
$$

Ideal refrigeration cycle with actual compressor

$$
\begin{aligned}
& \mathrm{T}_{\text {cond }}=18.88^{\circ} \mathrm{C}=\mathrm{T}_{\text {sat }} 1400 \mathrm{kPa} \\
& \mathrm{~T}_{2}=60^{\circ} \mathrm{C}
\end{aligned}
$$

$$
\mathrm{T}_{\text {evap }}=-20^{\circ} \mathrm{C}=\mathrm{T}_{1}
$$

Properties from Table B. 4

### 13.191

Two pound moles of ammonia are burned in a steady state process with $x \mathrm{lb} \mathrm{mol}$ of oxygen. The products, consisting of $\mathrm{H}_{2} \mathrm{O}, \mathrm{N}_{2}$, and the excess $\mathrm{O}_{2}$, exit at 400 F , $1000 \mathrm{lbf} / \mathrm{in} .^{2}$.
a. Calculate $x$ if half the water in the products is condensed.
b. Calculate the absolute entropy of the products at the exit conditions.

$$
2 \mathrm{NH}_{3}+\mathrm{xO}_{2} \rightarrow 3 \mathrm{H}_{2} \mathrm{O}+\mathrm{N}_{2}+(\mathrm{x}-1.5) \mathrm{O}_{2}
$$

Products at $400 \mathrm{~F}, 1000 \mathrm{lbf} / \mathrm{in}^{2}$ with $\mathrm{n}_{\mathrm{H} 2 \mathrm{O} \text { LIQ }}=\mathrm{n}_{\mathrm{H} 2 \mathrm{O} \text { VAP }}=1.5$
a) $\mathrm{y}_{\mathrm{H} 2 \mathrm{O} \text { VAP }}=\frac{\mathrm{P}_{\mathrm{G}}}{\mathrm{P}}=\frac{247.1}{1000}=\frac{1.5}{1.5+1+\mathrm{x}-1.5}$

$$
x=5.070
$$

b) $\mathrm{S}_{\text {PROD }}=\mathrm{S}_{\text {GAS MIX }}+\mathrm{S}_{\text {H2O LIQ }}$

Gas mixture:

|  | $\mathrm{n}_{\mathrm{i}}$ | $\mathrm{y}_{\mathrm{i}}$ | $\overline{\mathrm{s}}_{\mathrm{i}}^{\circ}$ | $-\overline{\mathrm{R}} \ln \frac{\mathrm{y}_{\mathrm{i}} \mathrm{P}}{\mathrm{P}_{0}}$ | $\overline{\mathrm{~S}}_{\mathrm{i}}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{H}_{2} \mathrm{O}$ | 1.5 | 0.2471 | 48.939 | -5.604 | 43.335 |
| $\mathrm{O}_{2}$ | 3.57 | 0.5881 | 52.366 | -7.326 | 45.040 |
| $\mathrm{~N}_{2}$ | 1.0 | 0.1648 | 49.049 | -4.800 | 44.249 |

$$
\begin{aligned}
& \mathrm{S}_{\mathrm{GAS} \text { MIX }}=1.5(43.335)+3.57(45.040)+1.0(44.249)=270.04 \mathrm{Btu} / \mathrm{R} \\
& \mathrm{~S}_{\mathrm{H} 2 \mathrm{O} \text { LIQ }}=1.5[16.707+18.015(0.5647-0.0877)]=37.95 \mathrm{Btu} / \mathrm{R} \\
& \mathrm{~S}_{\mathrm{PROD}}=270.04+37.95=\mathbf{3 0 7 . 9 9} \mathbf{B t u} / \mathbf{R}
\end{aligned}
$$
